Screwdrivers
all about those suckers

1. to ***cam out*** - when a driver bit jumps out a screw's slot due to a high torque .
    1. the bit ***cammed out at*** 80 in/lbs torque
2. the bit ***lost traction at*** 80 in / lbs (read like 80 inch-pounds)
3. to ***snap*** (of screws)
    1. When the torque is too much and the bit doesn't cam out the screw will inevitably snap .
4. Also a bit can easilly snap
5. the quickest way to destroy a driver bit is not applying enough ***downwards force***
6. also removing a bit when the ***driver's*** still in ***motion*** isn't a good idea
7. to ***strip / out*** - to damage or tear a thread or slot in a screw
    1. stripped screws
8. be careful and don't ***strip out*** the hole
9. to ***grip*** well - when a driver bit is fitted well in a screw
10. to have ***a good fit*** / ***to fit well*** (same as above)
11. to have a good ***grip of***(same)
12. to ***wobble*** / to ***have*** some ***wobble*** - when a bit sits a bit loosely in a screw
13. to have some wobble in (jointed parts) - when two joined parts get a bit loose
14. extreme ***torque loads***
15. ***high torque applications***
16. the middle part between the blade/tip and the handle of a screwdriver is called a ***shank*** or ***shaft*** .
17. Some screwdrivers have a metal ***striking cap*** on the top of the handle for applying a striking tools such as a hammer or mallet .
18. The shaft can start moving into the handle when experiences too much heavy hammering .
19. After some amount of screwing / unscrewing sessions the flutes of a philips or pozidriv bit can experience a lot of ***wear*** , ***material loss*** or just bend . Consequently they will require more downward pressure to prevent ***slipping out*** of a screw .
20. Flat head screwdrivers have a ***blade*** while philips and others alike have a ***tip*** on the working end of the shaft .
